PART 1: INTRODUCTION

The Binomial Distribution

- The binomial probability distribution is a discrete probability distribution that has many applications.

- It is associated with a multiple step experiment that we call the binomial experiment.

PART 2: THE BINOMIAL EXPERIMENT

The Binomial Distribution

A binomial experiment has the following properties.

<u>Property 1</u>

The binomial experiment consists of a sequence of **n** independent identical trials.

Throwing a coin ten times is an example of a binomial experiment .

The Binomial Distribution

<u>Property 2</u>

- Two, and only two, outcomes are possible at each trial. We refer to one as a "**success"** and the other as a "**failure"**.

- Throwing a "**head**" could thought of as a success, while throwing a "**tail**" could be thought of as a failure.

- In other examples, the "success" could refer to a randomly selected component could be found to be broken during an inspection.

The Binomial Distribution

<u>**Property 3**</u>

- The probability of a success, denoted by **p**, does not change from trial to trial.

- Similarly the probability of a failure, denoted by **1-p**, also does not change from trial to trial.

The Binomial Distribution

Property 4

- The trials are independent.
- The outcome of one trial does not have any effect on the outcome of the next.
- The fact that we have thrown a head in the last step doest not increase the chances of throwing a head in the next step.

Binomial Distribution

In a binomial experiment our interest is in the number of successes occurring in the ***n*** trials.

To find out the probability of a specified number of successes in **n** trials, given the probability of success **p,** we use the binomial probability distribution.

PART 3: THE BINOMIAL DISTRIBUTION FORMULA

Binomial Distribution

The formula for the probability distribution is as follows:

$$P(X=k)=\binom{n}{k}p^k(1-p)^{n-k}$$

We will now explain each term of this formula individually.

The Binomial Distribution

$$P(X = k)$$

This term denotes the probability (***P***) that number of successes (***X***) will be "***k***".

For example, the probability that the number of successes will be three is written as follows:

P(X=3)

The Binomial Distribution

$$\binom{n}{k}$$

This is the "***choose operator***".

This is used to calculate the number of ways ***k*** successes can occur in ***n*** trials.

The Binomial Distribution

$$p^k$$

This is the probability of a success ***p*** to the power of the number of successes ***k.***

.

The Binomial Distribution

$$(1-p)^{n-k}$$

This is the probability of a failure ***1-p*** to the power of the number of failures ***n-k.***

•

PART 4: AN SIMPLE EXAMPLE

Binomial Distribution

If we throw a coin 4 times, what is the probability that we do not throw a "head" on any of those four times.

Firstly we know that the number of trials is four (***n = 4***) . Also throwing a "***head***" is what constitutes a "success". (Throwing a tail is a "failure".)

Binomial Distribution

What is the probability that the number of success (***k***) is zero?

If we have zero successes out of four trials, the number of failures **(n-k**) must be four.

We assume that the probability of a success ***p*** , and of a failure ***1-p*** is 0.5 (50%)

Binomial Distribution

Here are our important values:

- $k=0$
- $n=4$
- $n-k = 4-0 = 4$
- $p=0.5$
- $1-p = 0.5$

Binomial Distribution

So what is the probability of no successes in four trials?

Assigning our values to the relevant positions in the formula we write

$$P(X=0)=\binom{4}{0}0.5^0\,(0.5)^4$$

Binomial Distribution

The value of the choose operator is 1.

$$\binom{4}{0} = 1$$

Again, we will refer to a MathsCast presentation that deals specifically with the choose operator, where a detailed explanation is provided.

Binomial Distribution

The any value to the power of zero is always one.

$$0.5^0 = 1$$

The last value is found using a calculator.

$$0.5^4 = 0.0625$$

Binomial Distribution

$$P(X=0)=\binom{4}{0}0.5^0(0.5)^4$$

$$P(X=0)=1\times1\times0.0625$$

$$P(X=0)=0.0625$$

Binomial Distribution

Therefore the probability of not throwing any heads in four throws of a coin is 6.25%

End of presentation.
